

1. Issues:

Title	Steps to find	Expected vs Actual	Severity	Suspected Cause
1. No Password Validation on Sign-up	Go to Sign Up -> Enter username, email -> type a 1-character password (e.g. 1) -> click Sign Up	Expected: Error saying "Password too short" Actual: Form submits with no warning. Weak password accepted	High	No-Client side or server-side password Policy enforced.
2. Navbar breaks on Mobile View	Open app on mobile or resize browser to < 480px width	Expected: Responsive hamburger menu or stacked nav. Actual: Nav Items overflow or collapse into broken layout.	Medium	No responsive CSS/Missing media queries for mobile breakpoints
3. Global Feed broken on Mobile View	Open home page on mobile viewport -> try scrolling/tapping feed tabs	Expected: The divider line should not overlap the content. Actual: The divider overlaps the content.	Medium	CSS layout not adapting to small screen, likely flexbox/grid not mobile-optimized.
4. JWT Token stored in Local Storage (Security)	Login -> Open DevTools (F12) -> Application -> Local Storage -> demo.realworld.show	Expected: Auth token stored securely (httpOnly cookie, not accessible to JS). Actual: JWT token visible in plain text in local Storage.	High	Token stored in JS-accessible storage, vulnerable to XSS.
5. No Delete confirmation dialog	Sign in -> create an article -> click delete button	Expected: Confirmation prompt: "Are you sure you want to delete the article?". Actual: Article is permanently on single click.	Medium	No confirmation or dialog implemented before destructive action.
6. Cryptic Error messages on login failure	Go to sign in -> Enter wrong email/password -> Submit	Expected: Specific message like "Email not found" or "Incorrect password". Actual: Generic message "Credential Invalid" with no actionable guidance	Low	Backend returns a single generic error; frontend does not parse or humanize it.

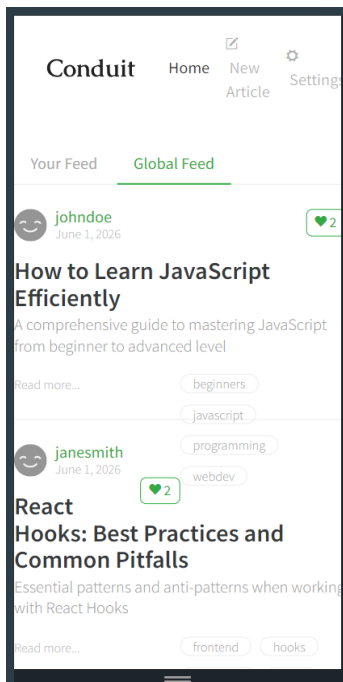

Images and Videos of the Bugs:

1. No password validation on signup:

Root-Cause Analysis:

- **No Password Validation during signup:**
 - **What is Happening:** The sign-up form accepts passwords of any length and complexity including single characters, without any client-side feedback to the user before submission.
 - **Why it is happening:** The root cause is a missing validation layer on the frontend. The application relies entirely on the server to reject bad input, but even the server's response does not enforce minimum password strength rules (length, special characters, etc.). In well-architected apps, validation should happen at two levels the browser (instant feedback) and the server (security enforcement). Here, neither is doing its job completely.
 - **What the user experiences:** A user can register with a password like '1' or 'abc' and the form either accepts it silently or returns a vague server error with no guidance on what a valid password looks like. There is no inline hint such as "Password must be at least 8 characters."

- **How to fix it:** On the frontend, add a validation function that checks password length (minimum 8 characters), and optionally requires at least one number or special character triggering inline error messages before the form is even submitted. On the backend, enforce the same rules server-side as a second line of defence, returning a clear, specific error message if the rule is violated.
